

CSE408

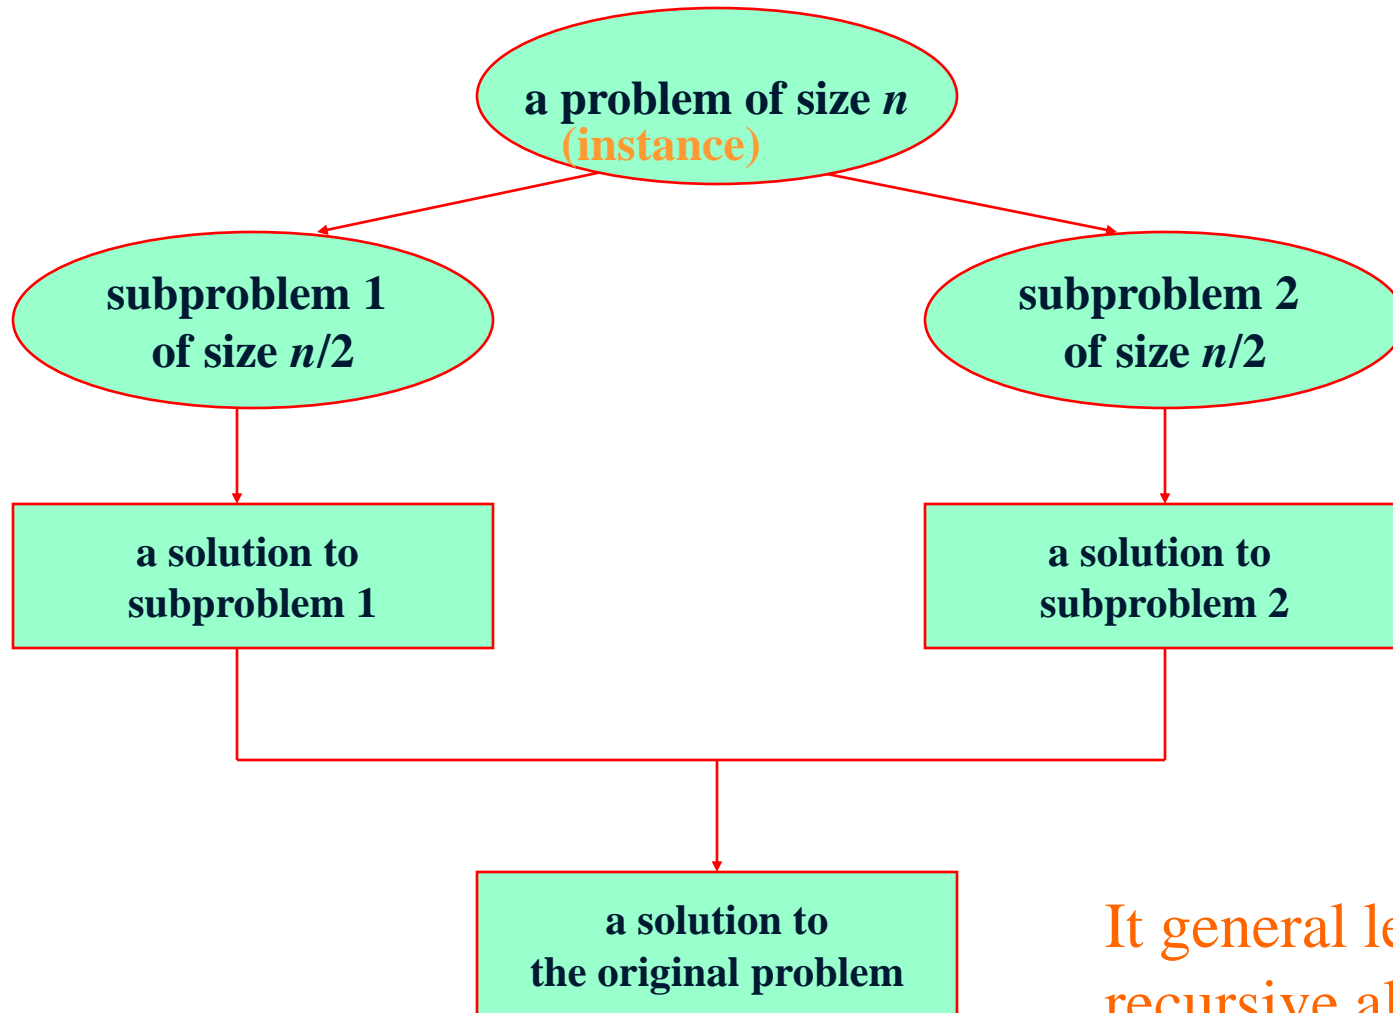

Divide and Conquer

Lecture #9&10

The most-well known algorithm design strategy:

1. Divide instance of problem into two or more smaller instances
2. Solve smaller instances recursively
3. Obtain solution to original (larger) instance by combining these solutions

Divide-and-Conquer Technique (cont.)

It general leads to a recursive algorithm!

Divide-and-Conquer Examples

- Sorting: mergesort and quicksort
- Binary tree traversals
- Binary search (?)
- Multiplication of large integers
- Matrix multiplication: Strassen's algorithm
- Closest-pair and convex-hull algorithms

General Divide-and-Conquer Recurrence

$$T(n) = aT(n/b) + f(n) \quad \text{where } f(n) \in \Theta(n^d), \quad d \geq 0$$

Master Theorem: If $a < b^d$, $T(n) \in \Theta(n^d)$

If $a = b^d$, $T(n) \in \Theta(n^d \log n)$

If $a > b^d$, $T(n) \in \Theta(n^{\log_b a})$

Note: The same results hold with O instead of Θ .

Examples: $T(n) = 4T(n/2) + n \Rightarrow T(n) \in ?$ $\Theta(n^2)$

$T(n) = 4T(n/2) + n^2 \Rightarrow T(n) \in ?$ $\Theta(n^2 \log n)$

$T(n) = 4T(n/2) + n^3 \Rightarrow T(n) \in ?$ $\Theta(n^3)$

- Split array $A[0..n-1]$ into about equal halves and make copies of each half in arrays B and C
- Sort arrays B and C recursively
- Merge sorted arrays B and C into array A as follows:
 - Repeat the following until no elements remain in one of the arrays:
 - compare the first elements in the remaining unprocessed portions of the arrays
 - copy the smaller of the two into A, while incrementing the index indicating the unprocessed portion of that array
 - Once all elements in one of the arrays are processed, copy the remaining unprocessed elements from the other array into A.

Pseudocode of Mergesort

ALGORITHM *Mergesort*($A[0..n - 1]$)

//Sorts array $A[0..n - 1]$ by recursive mergesort

//Input: An array $A[0..n - 1]$ of orderable elements

//Output: Array $A[0..n - 1]$ sorted in nondecreasing order

if $n > 1$

 copy $A[0..\lfloor n/2 \rfloor - 1]$ to $B[0..\lfloor n/2 \rfloor - 1]$

 copy $A[\lfloor n/2 \rfloor..n - 1]$ to $C[0..\lceil n/2 \rceil - 1]$

Mergesort($B[0..\lfloor n/2 \rfloor - 1]$)

Mergesort($C[0..\lceil n/2 \rceil - 1]$)

 Merge(B, C, A)

Pseudocode of Merge

ALGORITHM $Merge(B[0..p-1], C[0..q-1], A[0..p+q-1])$

//Merges two sorted arrays into one sorted array

//Input: Arrays $B[0..p-1]$ and $C[0..q-1]$ both sorted

//Output: Sorted array $A[0..p+q-1]$ of the elements of B and C

$i \leftarrow 0; j \leftarrow 0; k \leftarrow 0$

while $i < p$ **and** $j < q$ **do**

if $B[i] \leq C[j]$

$A[k] \leftarrow B[i]; i \leftarrow i + 1$

else $A[k] \leftarrow C[j]; j \leftarrow j + 1$

$k \leftarrow k + 1$

if $i = p$

 copy $C[j..q-1]$ to $A[k..p+q-1]$

else copy $B[i..p-1]$ to $A[k..p+q-1]$

Time complexity: $\Theta(p+q) = \Theta(n)$ comparisons

Mergesort Example

The non-recursive version of Mergesort starts from merging single elements into sorted pairs.

Analysis of Mergesort

- All cases have same efficiency: $\Theta(n \log n)$

$$T(n) = 2T(n/2) + \Theta(n), \quad T(1) = 0$$

- Number of comparisons in the worst case is close to theoretical minimum for comparison-based sorting:

$$\lceil \log_2 n! \rceil \approx n \log_2 n - 1.44n$$

- Space requirement: $\Theta(n)$ (not in-place)
- Can be implemented without recursion (bottom-up)

- Select a *pivot* (partitioning element) – here, the first element
- Rearrange the list so that all the elements in the first s positions are smaller than or equal to the pivot and all the elements in the remaining $n-s$ positions are larger than or equal to the pivot (see next slide for an algorithm)

- Exchange the pivot with the last element in the first (i.e., \leq) subarray — the pivot is now in its final position
- Sort the two subarrays recursively

Partitioning Algorithm

```
Algorithm Partition( $A[l..r]$ )
//Partitions a subarray by using its first element as a pivot
//Input: A subarray  $A[l..r]$  of  $A[0..n - 1]$ , defined by its left and right
//      indices  $l$  and  $r$  ( $l < r$ )
//Output: A partition of  $A[l..r]$ , with the split position returned as
//      this function's value
 $p \leftarrow A[l]$ 
 $i \leftarrow l; \quad j \leftarrow r + 1$ 
repeat
    repeat  $i \leftarrow i + 1$  until  $A[i] \geq p$ 
    repeat  $j \leftarrow j - 1$  until  $A[j] < p$ 
    swap( $A[i], A[j]$ )
until  $i \geq j$ 
swap( $A[i], A[j]$ ) //undo last swap when  $i \geq j$ 
swap( $A[l], A[j]$ )
return  $j$ 
```

Time complexity: $\Theta(r-l)$ comparisons

Analysis of Quicksort

- Best case: split in the middle — $\Theta(n \log n)$
- Worst case: sorted array! — $\Theta(n^2)$ $T(n) = T(n-1) + \Theta(n)$
- Average case: random arrays — $\Theta(n \log n)$

- Improvements:
 - better pivot selection: median of three partitioning
 - switch to insertion sort on small subfiles
 - elimination of recursion

These combine to 20-25% improvement

- Considered the method of choice for internal sorting of large files ($n \geq 10000$)

Divide: Partition (rearrange) the array $A[p \dots r]$ into two (possibly empty) subarrays $A[p \dots q - 1]$ and $A[q + 1 \dots r]$ such that each element of $A[p \dots q - 1]$ is less than or equal to $A[q]$, which is, in turn, less than or equal to each element of $A[q + 1 \dots r]$. Compute the index q as part of this partitioning procedure.

Conquer: Sort the two subarrays $A[p \dots q - 1]$ and $A[q + 1 \dots r]$ by recursive calls to quicksort.

The following procedure implements quicksort:

QUICKSORT(A, p, r)

```
1  if  $p < r$ 
2       $q = \text{PARTITION}(A, p, r)$ 
3      QUICKSORT( $A, p, q - 1$ )
4      QUICKSORT( $A, q + 1, r$ )
```

To sort an entire array A , the initial call is QUICKSORT($A, 1, A.length$).

Partitioning the array

The key to the algorithm is the PARTITION procedure, which rearranges the subarray $A[p..r]$ in place.

PARTITION(A, p, r)

```
1   $x = A[r]$ 
2   $i = p - 1$ 
3  for  $j = p$  to  $r - 1$ 
4      if  $A[j] \leq x$ 
5           $i = i + 1$ 
6          exchange  $A[i]$  with  $A[j]$ 
7  exchange  $A[i + 1]$  with  $A[r]$ 
8  return  $i + 1$ 
```

Figure 7.2 The four regions maintained by the procedure PARTITION on a subarray $A[p..r]$. The values in $A[p..i]$ are all less than or equal to x , the values in $A[i+1..j-1]$ are all greater than x , and $A[r] = x$. The subarray $A[j..r-1]$ can take on any values.

WORST CASE

$$\begin{aligned} T(n) &= T(n-1) + T(0) + \Theta(n) \\ &= T(n-1) + \Theta(n) . \end{aligned}$$

$$T(n) = 2T(n/2) + \Theta(n) ,$$

As an example, let us apply binary search to searching for $K = 70$ in the array

3	14	27	31	39	42	55	70	74	81	85	93	98
---	----	----	----	----	----	----	----	----	----	----	----	----

The iterations of the algorithm are given in the following table:

index	0	1	2	3	4	5	6	7	8	9	10	11	12
value	3	14	27	31	39	42	55	70	74	81	85	93	98
iteration 1	l						m						r
iteration 2								l		m			r
iteration 3								l, m	r				

Binary Search

Very efficient algorithm for searching in sorted array:

K

vs

$A[0] \dots A[m] \dots A[n-1]$

If $K = A[m]$, stop (successful search); otherwise, continue searching by the same method in $A[0..m-1]$ if $K < A[m]$ and in $A[m+1..n-1]$ if $K > A[m]$

$l \leftarrow 0; \quad r \leftarrow n-1$

while $l \leq r$ do

$m \leftarrow \lfloor (l+r)/2 \rfloor$

 if $K = A[m]$ return m

 else if $K < A[m]$ $r \leftarrow m-1$

 else $l \leftarrow m+1$

return -1

Analysis of Binary Search

- Time efficiency
 - worst-case recurrence: $C_w(n) = 1 + C_w(\lfloor n/2 \rfloor)$, $C_w(1) = 1$
solution: $C_w(n) = \lceil \log_2(n+1) \rceil$

This is VERY fast: e.g., $C_w(10^6) = 20$

- Optimal for searching a sorted array
- Limitations: must be a sorted array (not linked list)
- Bad (degenerate) example of divide-and-conquer because only one of the sub-instances is solved
- Has a continuous counterpart called *bisection method* for solving equations in one unknown $f(x) = 0$ (see Sec. 12.4)

Binary Tree Algorithms

Binary tree is a divide-and-conquer ready structure!

Ex. 1: Classic traversals (preorder, inorder, postorder)

Algorithm *Inorder*(T)

if $T \neq \emptyset$

Inorder(T_{left})

print(root of T)

Inorder(T_{right})

Efficiency: $\Theta(n)$. Why?

Ex. 2: Computing the height of a binary tree

$$h(T) = \max\{h(T_L), h(T_R)\} + 1 \text{ if } T \neq \emptyset \text{ and } h(\emptyset) = -1$$

Efficiency: $\Theta(n)$. Why?

Multiplication of Large Integers

Consider the problem of multiplying two (large) n -digit integers represented by arrays of their digits such as:

$$A = 12345678901357986429 \quad B = 87654321284820912836$$

The grade-school algorithm:

$$\begin{array}{r} a_1 \ a_2 \ \dots \ a_n \\ b_1 \ b_2 \ \dots \ b_n \\ \hline (d_{10}) \ d_{11} d_{12} \ \dots \ d_{1n} \\ (d_{20}) \ d_{21} d_{22} \ \dots \ d_{2n} \\ \dots \ \dots \ \dots \ \dots \ \dots \ \dots \ \dots \\ \hline (d_{n0}) \ d_{n1} d_{n2} \ \dots \ d_{nn} \end{array}$$

Efficiency: $\Theta(n^2)$ single-digit multiplications

First Divide-and-Conquer Algorithm

A small example: $A * B$ where $A = 2135$ and $B = 4014$

$$A = (21 \cdot 10^2 + 35), \quad B = (40 \cdot 10^2 + 14)$$

$$\text{So, } A * B = (21 \cdot 10^2 + 35) * (40 \cdot 10^2 + 14)$$

$$= 21 * 40 \cdot 10^4 + (21 * 14 + 35 * 40) \cdot 10^2 + 35 * 14$$

In general, if $A = A_1A_2$ and $B = B_1B_2$ (where A and B are n -digit, A_1, A_2, B_1, B_2 are $n/2$ -digit numbers),

$$A * B = A_1 * B_1 \cdot 10^n + (A_1 * B_2 + A_2 * B_1) \cdot 10^{n/2} + A_2 * B_2$$

Recurrence for the number of one-digit multiplications $M(n)$:

$$M(n) = 4M(n/2), \quad M(1) = 1$$

Solution: $M(n) = n^2$

$$c = a * b = c_2 10^2 + c_1 10^1 + c_0,$$

where

$c_2 = a_1 * b_1$ is the product of their first digits,

$c_0 = a_0 * b_0$ is the product of their second digits,

$c_1 = (a_1 + a_0) * (b_1 + b_0) - (c_2 + c_0)$ is the product of the sum of the a 's digits and the sum of the b 's digits minus the sum of c_2 and c_0 .

Now we apply this trick to multiplying two n -digit integers a and b where n is a positive even number. Let us divide both numbers in the middle—after all, we promised to take advantage of the divide-and-conquer technique. We denote the first half of the a 's digits by a_1 and the second half by a_0 ; for b , the notations are b_1 and b_0 , respectively. In these notations, $a = a_1a_0$ implies that $a = a_110^{n/2} + a_0$ and $b = b_1b_0$ implies that $b = b_110^{n/2} + b_0$. Therefore, taking advantage of the same trick we used for two-digit numbers, we get

$$\begin{aligned}c &= a * b = (a_1 10^{n/2} + a_0) * (b_1 10^{n/2} + b_0) \\&= (a_1 * b_1) 10^n + (a_1 * b_0 + a_0 * b_1) 10^{n/2} + (a_0 * b_0) \\&= c_2 10^n + c_1 10^{n/2} + c_0,\end{aligned}$$

where

$c_2 = a_1 * b_1$ is the product of their first halves,

$c_0 = a_0 * b_0$ is the product of their second halves,

$c_1 = (a_1 + a_0) * (b_1 + b_0) - (c_2 + c_0)$ is the product of the sum of the a 's halves and the sum of the b 's halves minus the sum of c_2 and c_0 .

Second Divide-and-Conquer Algorithm

$$\mathbf{A} * \mathbf{B} = \mathbf{A}_1 * \mathbf{B}_1 \cdot 10^n + (\mathbf{A}_1 * \mathbf{B}_2 + \mathbf{A}_2 * \mathbf{B}_1) \cdot 10^{n/2} + \mathbf{A}_2 * \mathbf{B}_2$$

The idea is to decrease the number of multiplications from 4 to 3:

$$(\mathbf{A}_1 + \mathbf{A}_2) * (\mathbf{B}_1 + \mathbf{B}_2) = \mathbf{A}_1 * \mathbf{B}_1 + (\mathbf{A}_1 * \mathbf{B}_2 + \mathbf{A}_2 * \mathbf{B}_1) + \mathbf{A}_2 * \mathbf{B}_2,$$

I.e., $(\mathbf{A}_1 * \mathbf{B}_2 + \mathbf{A}_2 * \mathbf{B}_1) = (\mathbf{A}_1 + \mathbf{A}_2) * (\mathbf{B}_1 + \mathbf{B}_2) - \mathbf{A}_1 * \mathbf{B}_1 - \mathbf{A}_2 * \mathbf{B}_2$,
which requires only 3 multiplications at the expense of (4-1) extra
add/sub.

Recurrence for the number of multiplications $M(n)$:

$$M(n) = 3M(n/2), \quad M(1) = 1$$

$$\text{Solution: } M(n) = 3^{\log_2 n} = n^{\log_2 3} \approx n^{1.585}$$

What if we count
both multiplications
and additions?

Example of Large-Integer Multiplication

$$2135 * 4014$$

$$= (21 * 10^2 + 35) * (40 * 10^2 + 14)$$

$$= (21 * 40) * 10^4 + c1 * 10^2 + 35 * 14$$

where $c1 = (21 + 35) * (40 + 14) - 21 * 40 - 35 * 14$, and

$$21 * 40 = (2 * 10 + 1) * (4 * 10 + 0)$$

$$= (2 * 4) * 10^2 + c2 * 10 + 1 * 0$$

where $c2 = (2 + 1) * (4 + 0) - 2 * 4 - 1 * 0$, etc.

This process requires 9 digit multiplications as opposed to 16.

$$M(n) = 3M(n/2) \quad \text{for } n > 1, \quad M(1) = 1.$$

Solving it by backward substitutions for $n = 2^k$ yields

$$\begin{aligned} M(2^k) &= 3M(2^{k-1}) = 3[3M(2^{k-2})] = 3^2 M(2^{k-2}) \\ &= \dots = 3^i M(2^{k-i}) = \dots = 3^k M(2^{k-k}) = 3^k. \end{aligned}$$

Since $k = \log_2 n$,

$$M(n) = 3^{\log_2 n} = n^{\log_2 3} \approx n^{1.585}.$$

(On the last step, we took advantage of the following property of logarithms:
 $a^{\log_b c} = c^{\log_b a}$.)

Conventional Matrix Multiplication

- Brute-force algorithm

$$\begin{pmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{pmatrix} = \begin{pmatrix} a_{00} & a_{01} \\ a_{10} & a_{11} \end{pmatrix} * \begin{pmatrix} b_{00} & b_{01} \\ b_{10} & b_{11} \end{pmatrix}$$

$$= \begin{pmatrix} a_{00} * b_{00} + a_{01} * b_{10} & a_{00} * b_{01} + a_{01} * b_{11} \\ a_{10} * b_{00} + a_{11} * b_{10} & a_{10} * b_{01} + a_{11} * b_{11} \end{pmatrix}$$

8 multiplications

4 additions

Strassen's Matrix Multiplication

- Strassen's algorithm for two 2x2 matrices (1969):

$$\begin{pmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{pmatrix} = \begin{pmatrix} a_{00} & a_{01} \\ a_{10} & a_{11} \end{pmatrix} * \begin{pmatrix} b_{00} & b_{01} \\ b_{10} & b_{11} \end{pmatrix}$$

$$= \begin{pmatrix} m_1 + m_4 - m_5 + m_7 & m_3 + m_5 \\ m_2 + m_4 & m_1 + m_3 - m_2 + m_6 \end{pmatrix}$$

- $m_1 = (a_{00} + a_{11}) * (b_{00} + b_{11})$
- $m_2 = (a_{10} + a_{11}) * b_{00}$
- $m_3 = a_{00} * (b_{01} - b_{11})$
- $m_4 = a_{11} * (b_{10} - b_{00})$
- $m_5 = (a_{00} + a_{01}) * b_{11}$
- $m_6 = (a_{10} - a_{00}) * (b_{00} + b_{01})$
- $m_7 = (a_{01} - a_{11}) * (b_{10} + b_{11})$

7 multiplications

18 additions

Strassen's Matrix Multiplication

Strassen observed [1969] that the product of two matrices can be computed in general as follows:

$$\begin{pmatrix} C_{00} & C_{01} \\ C_{10} & C_{11} \end{pmatrix} = \begin{pmatrix} A_{00} & A_{01} \\ A_{10} & A_{11} \end{pmatrix} * \begin{pmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{pmatrix}$$
$$= \begin{pmatrix} M_1 + M_4 - M_5 + M_7 & M_3 + M_5 \\ M_2 + M_4 & M_1 + M_3 - M_2 + M_6 \end{pmatrix}$$

Formulas for Strassen's Algorithm

$$M_1 = (A_{00} + A_{11}) * (B_{00} + B_{11})$$

$$M_2 = (A_{10} + A_{11}) * B_{00}$$

$$M_3 = A_{00} * (B_{01} - B_{11})$$

$$M_4 = A_{11} * (B_{10} - B_{00})$$

$$M_5 = (A_{00} + A_{01}) * B_{11}$$

$$M_6 = (A_{10} - A_{00}) * (B_{00} + B_{01})$$

$$M_7 = (A_{01} - A_{11}) * (B_{10} + B_{11})$$

Analysis of Strassen's Algorithm

If n is not a power of 2, matrices can be padded with zeros.

What if we count both
multiplications and additions?

Number of multiplications:

$$M(n) = 7M(n/2), \quad M(1) = 1$$

Solution: $M(n) = 7^{\log_2 n} = n^{\log_2 7} \approx n^{2.807}$ vs. n^3 of brute-force alg.

Algorithms with better asymptotic efficiency are known but they are even more complex and not used in practice.
